# Natural Disasters 1950-2009

285 Loss events

2 million fatalities

 Geophysical events  
(Earthquake, tsunami,  
volcanic eruption)

 Meteorological events  
(Storm)

 Hydrological events  
(Flood, mass movement)

 Climatological events  
(Extreme temperature,  
drought, forest fire)

**If earthquakes are the deadliest  
of all natural disasters,**

**what can we do about it?**

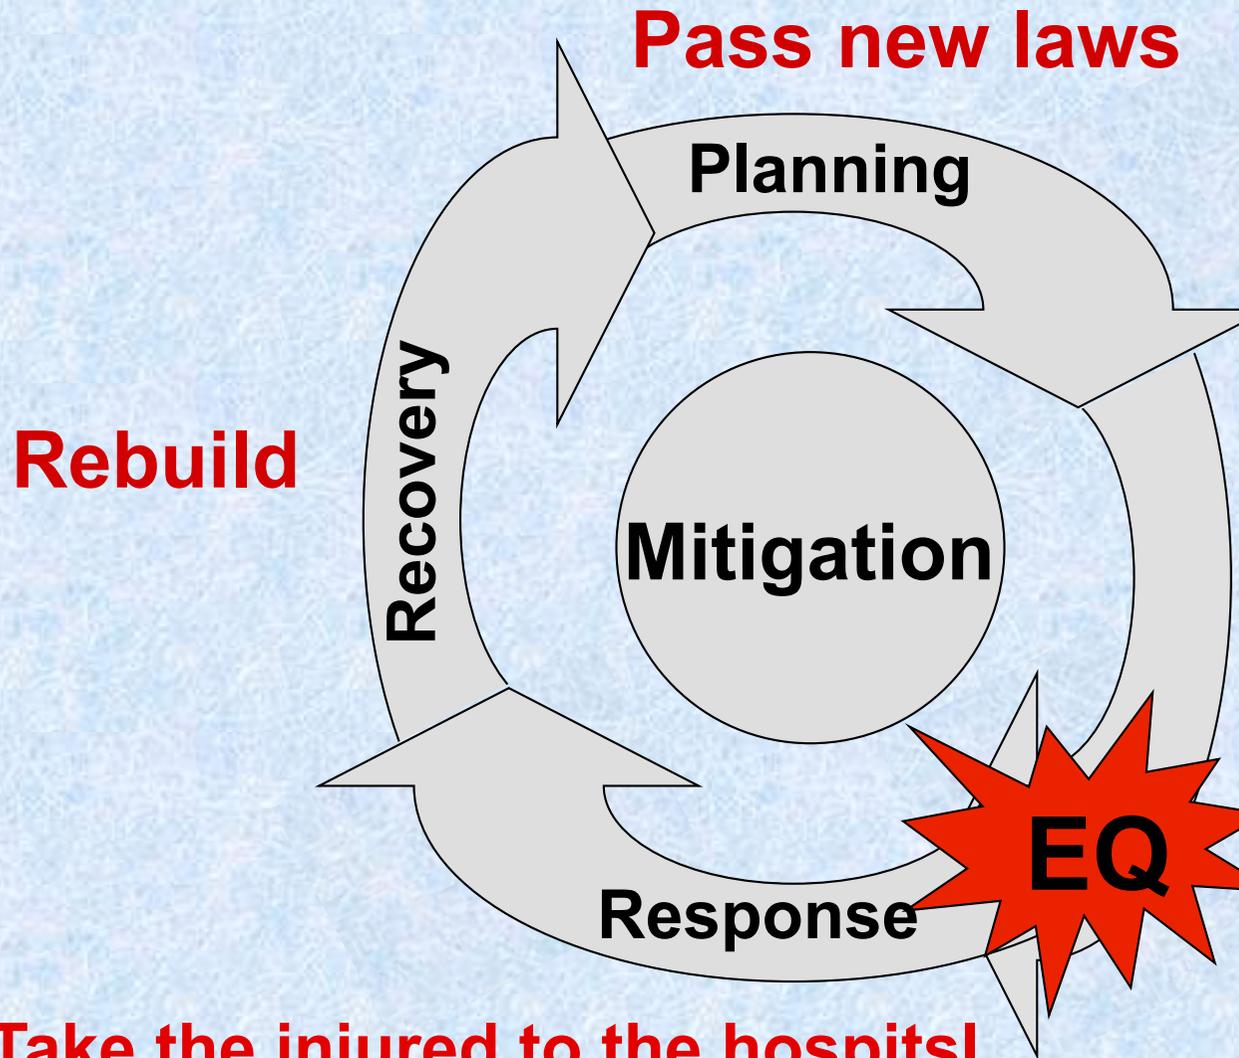

**Prominent seismologists have proclaimed**

**“Earthquakes cannot be predicted”**

**Robert Geller, 1997**

**...and (almost) everybody believes them.**

# Disaster Management Cycle

**Pass new laws**

**Planning**

**Rebuild**

**Recovery**

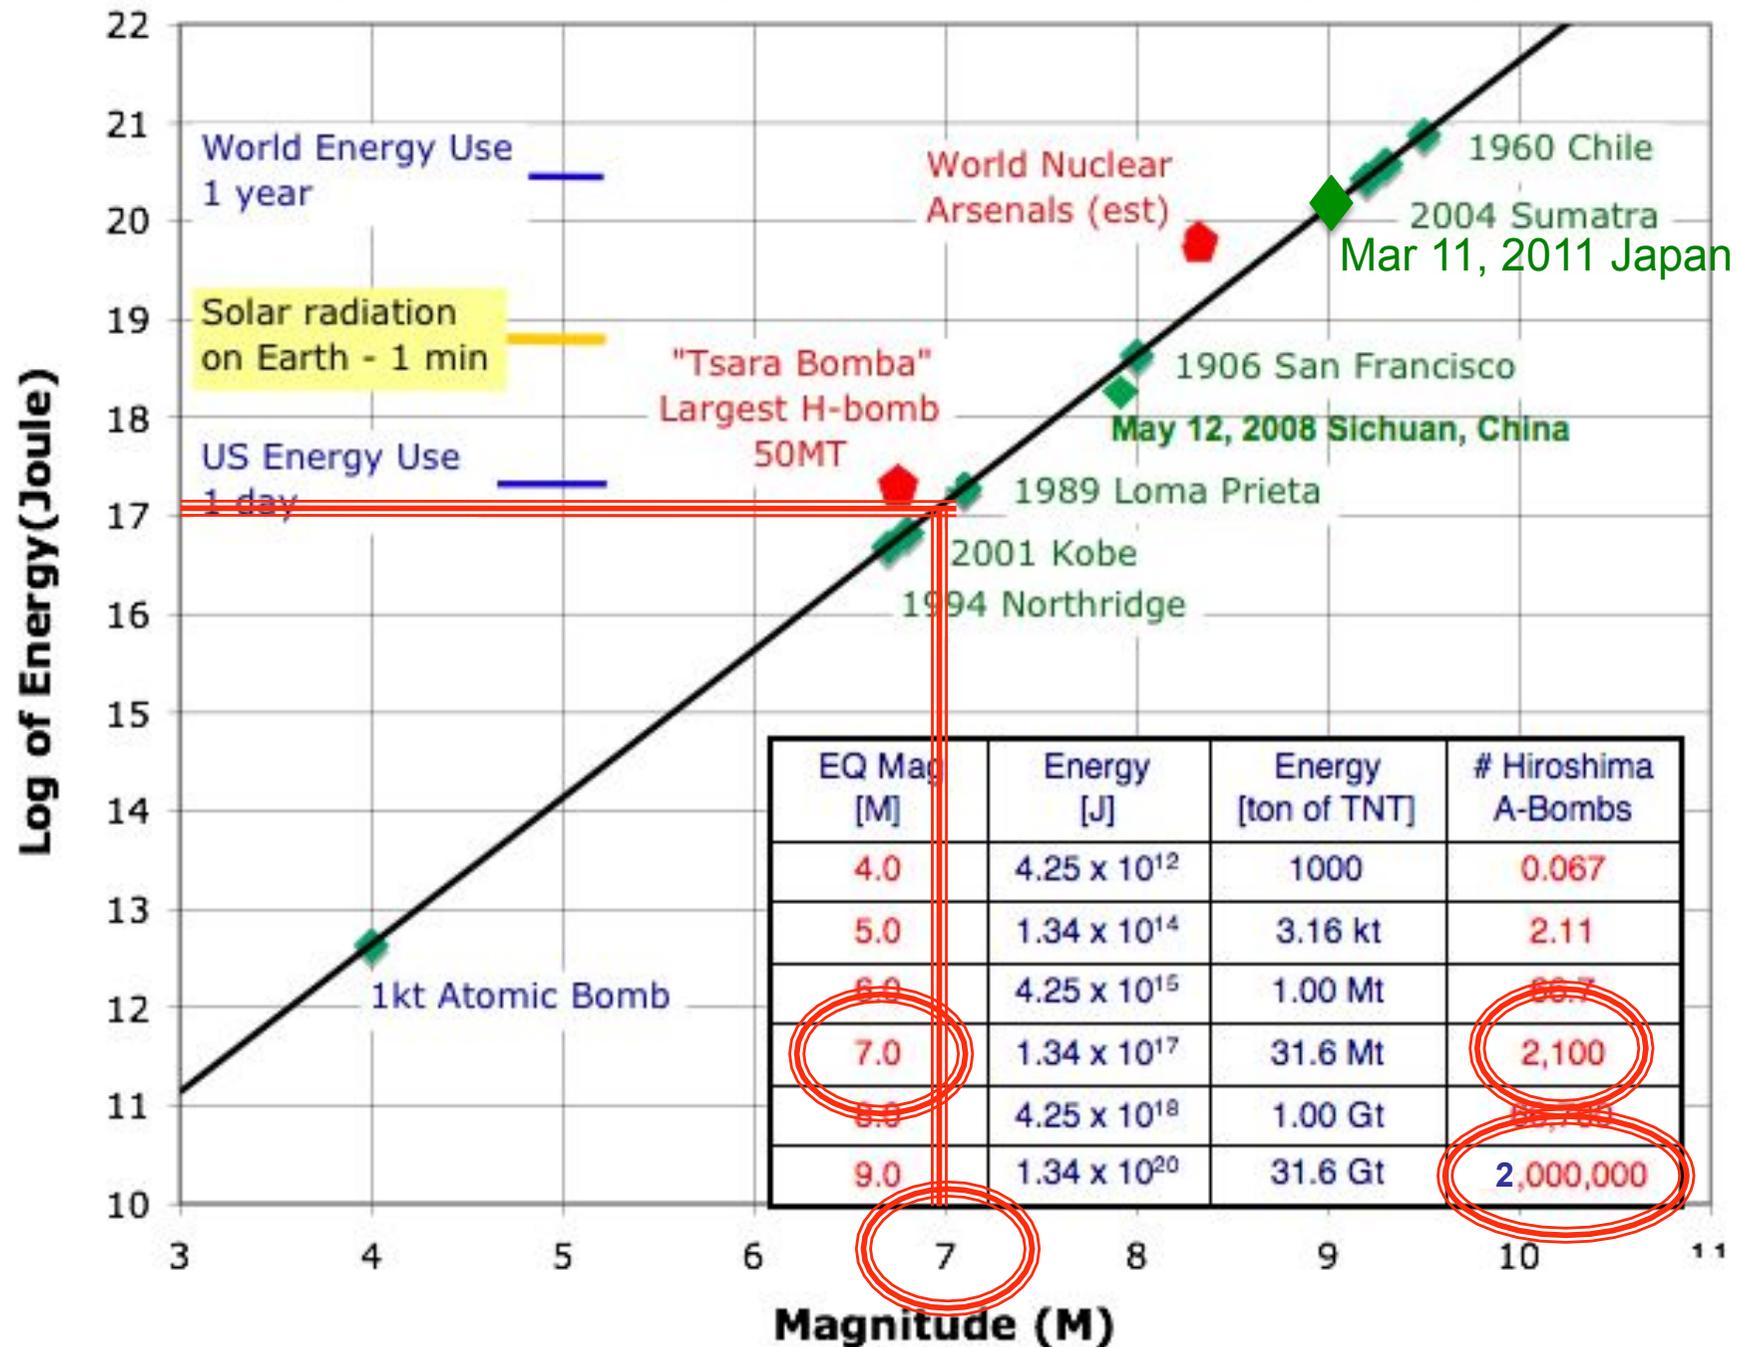

**Mitigation**

**Response**

**Sit and wait  
and wait  
and wait  
until the  
next one  
hits**

**Take the injured to the hospitals  
and the dead to the morgue**

# Comparing EQ's with other known events and energy scales

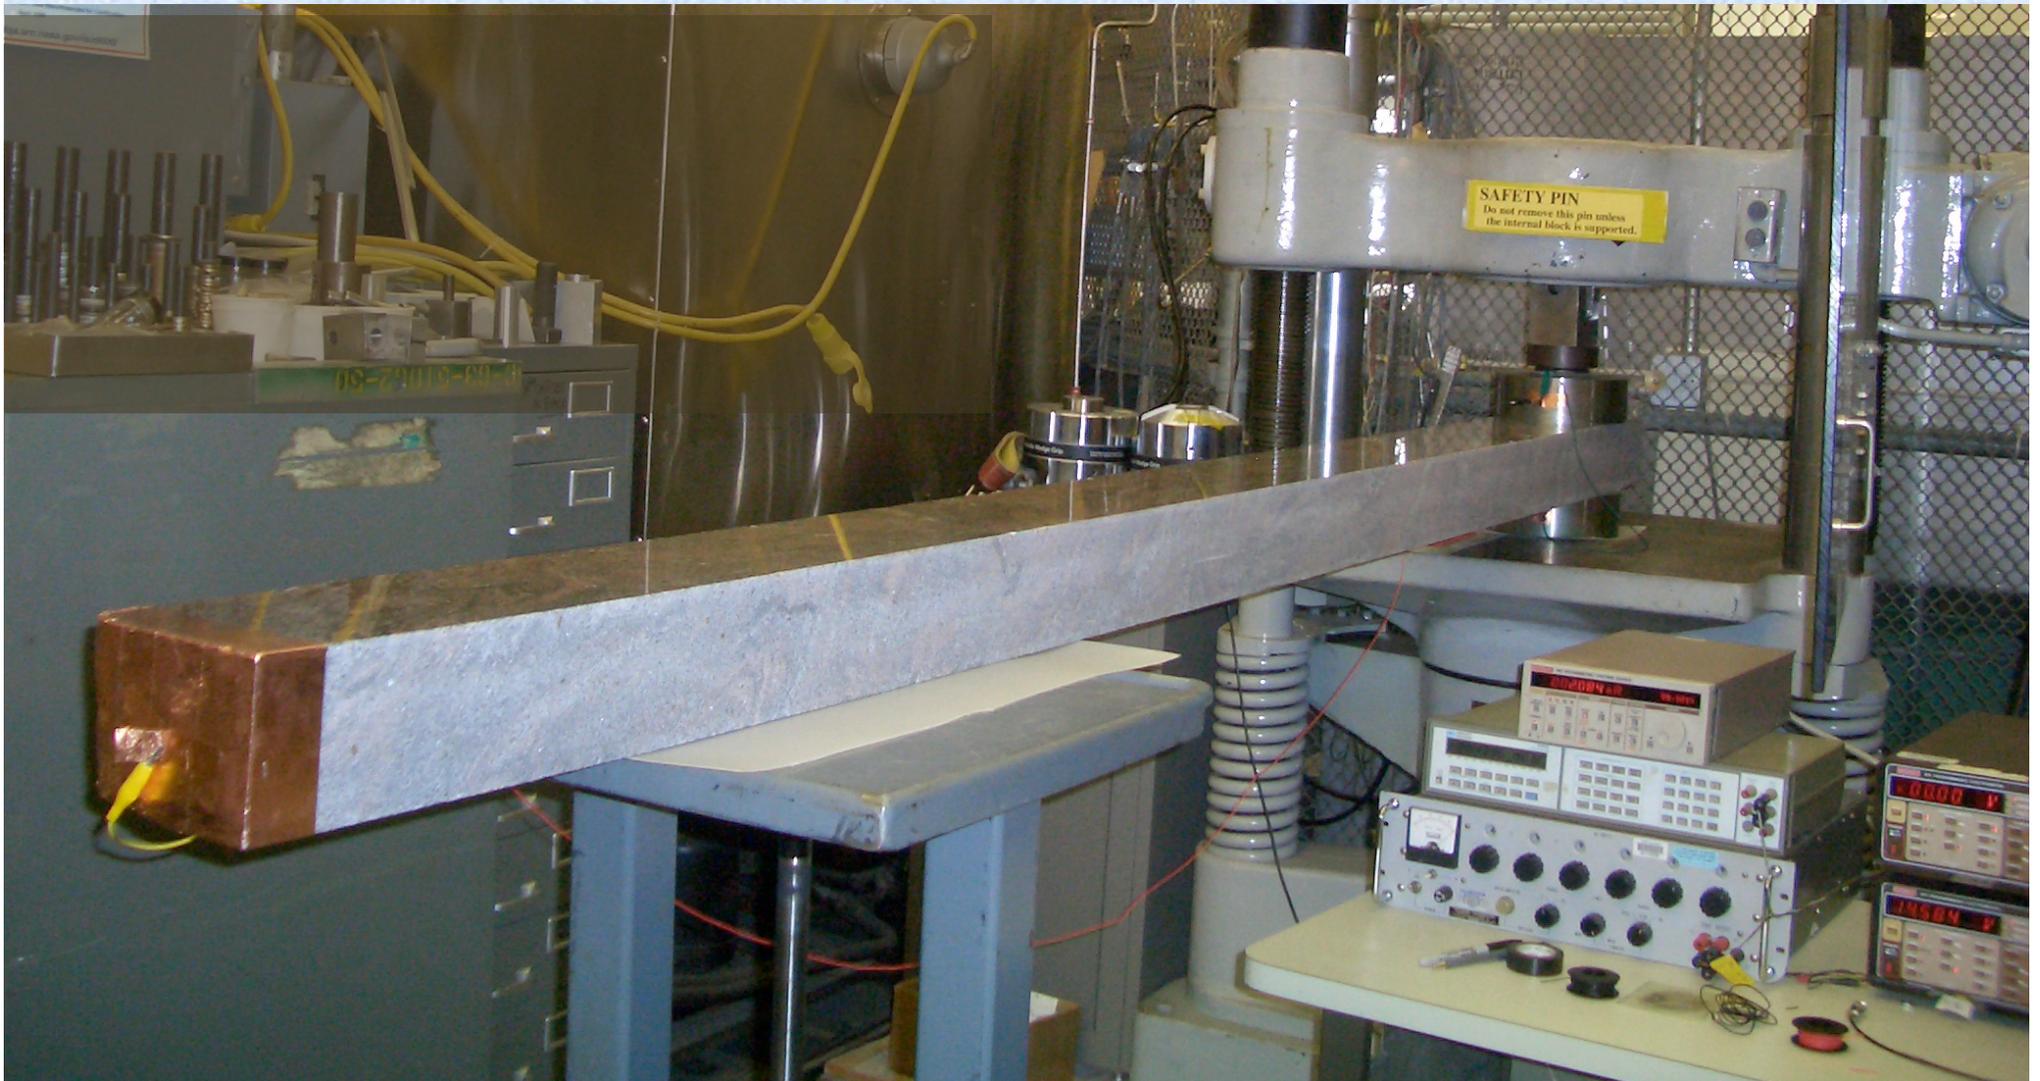

**If an M 9 earthquake releases  
energy equivalent to  
more than 2,000,000 Hiroshima A-bombs,  
*it's even more inconceivable***

**Surely seismologists  
didn't look at the right place**

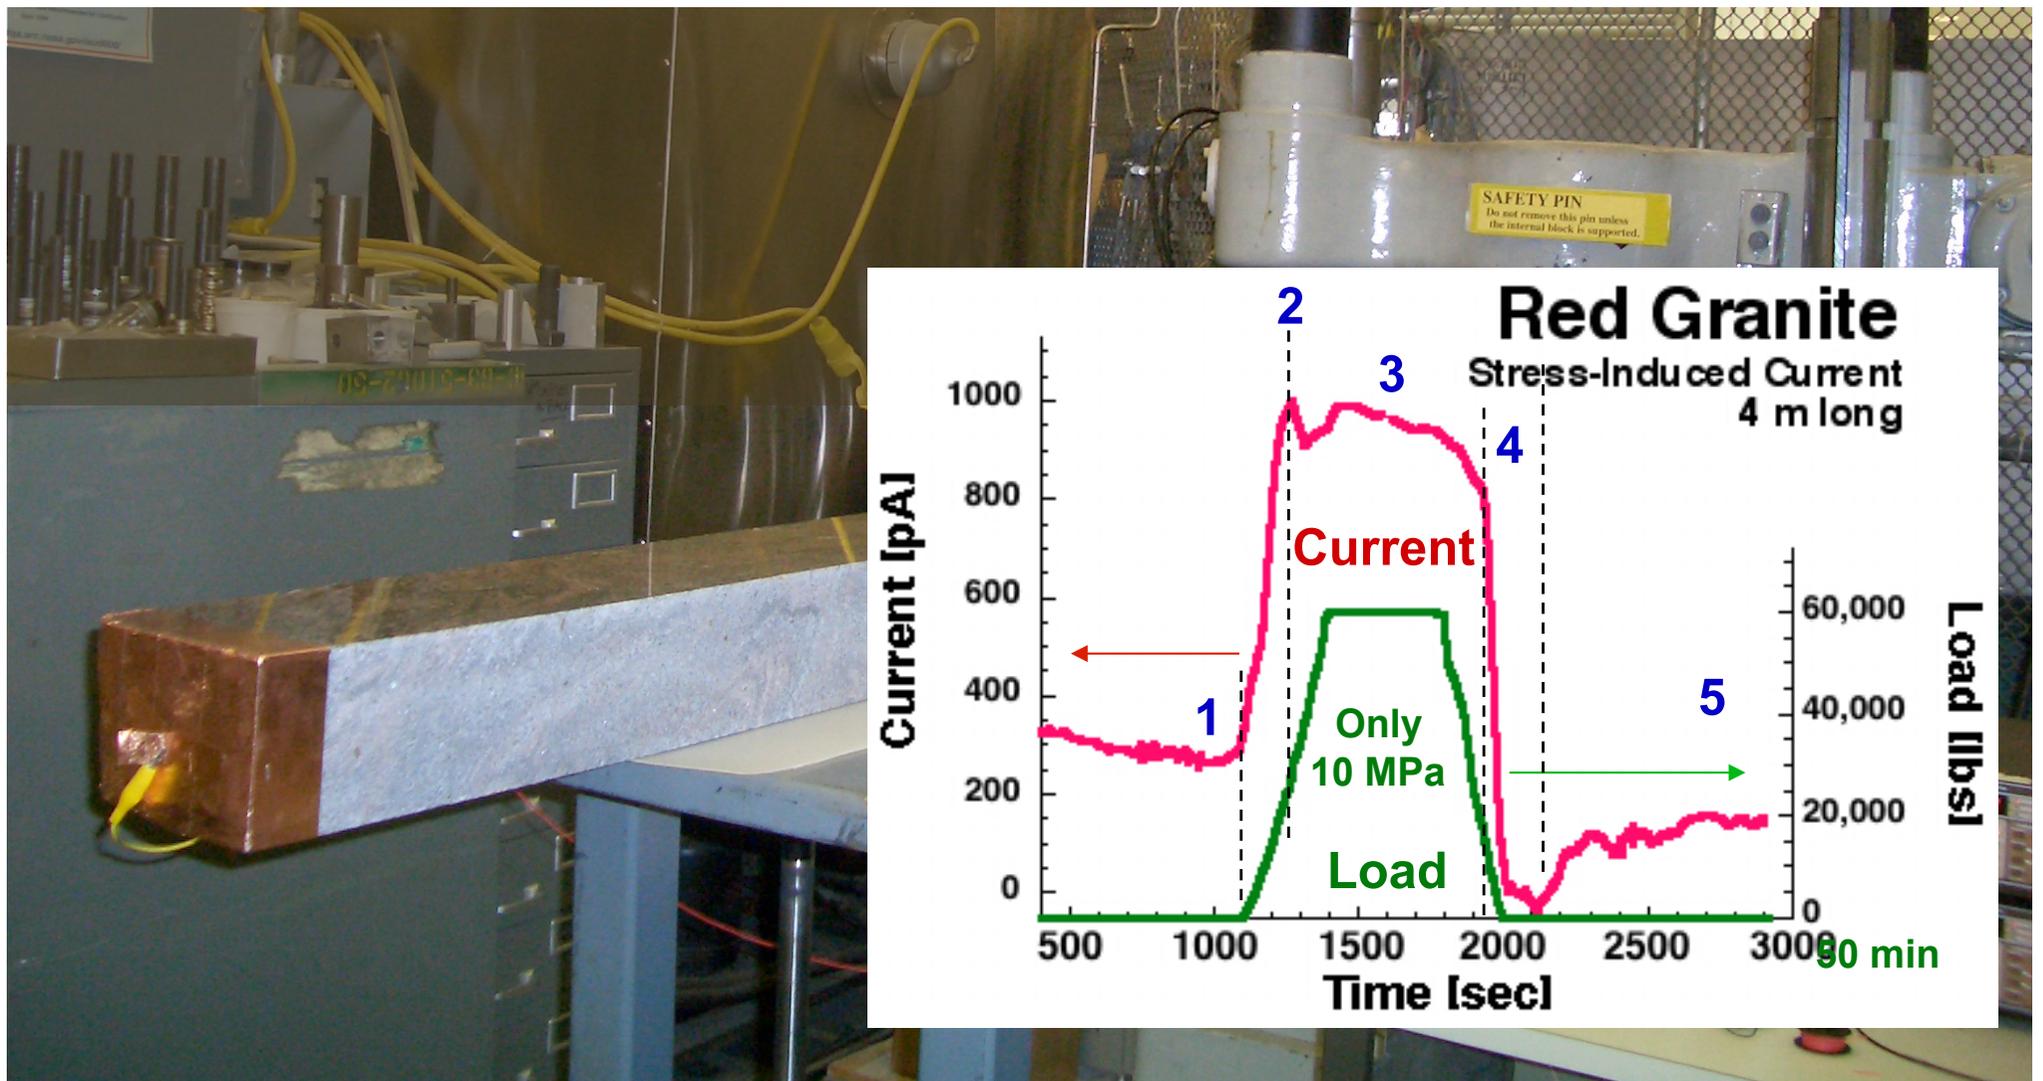

**Let's do a simple laboratory experiment  
that nobody has ever done before:**

**Take a rock and squeeze it at one end...**

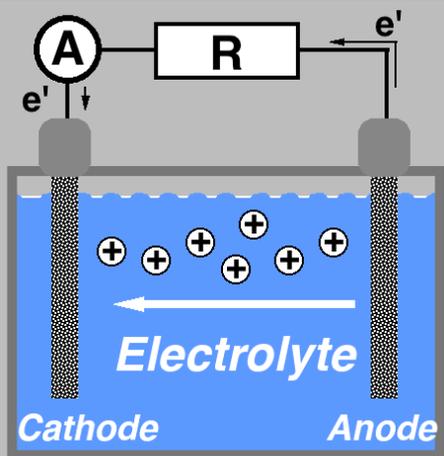

**What do you expect?**

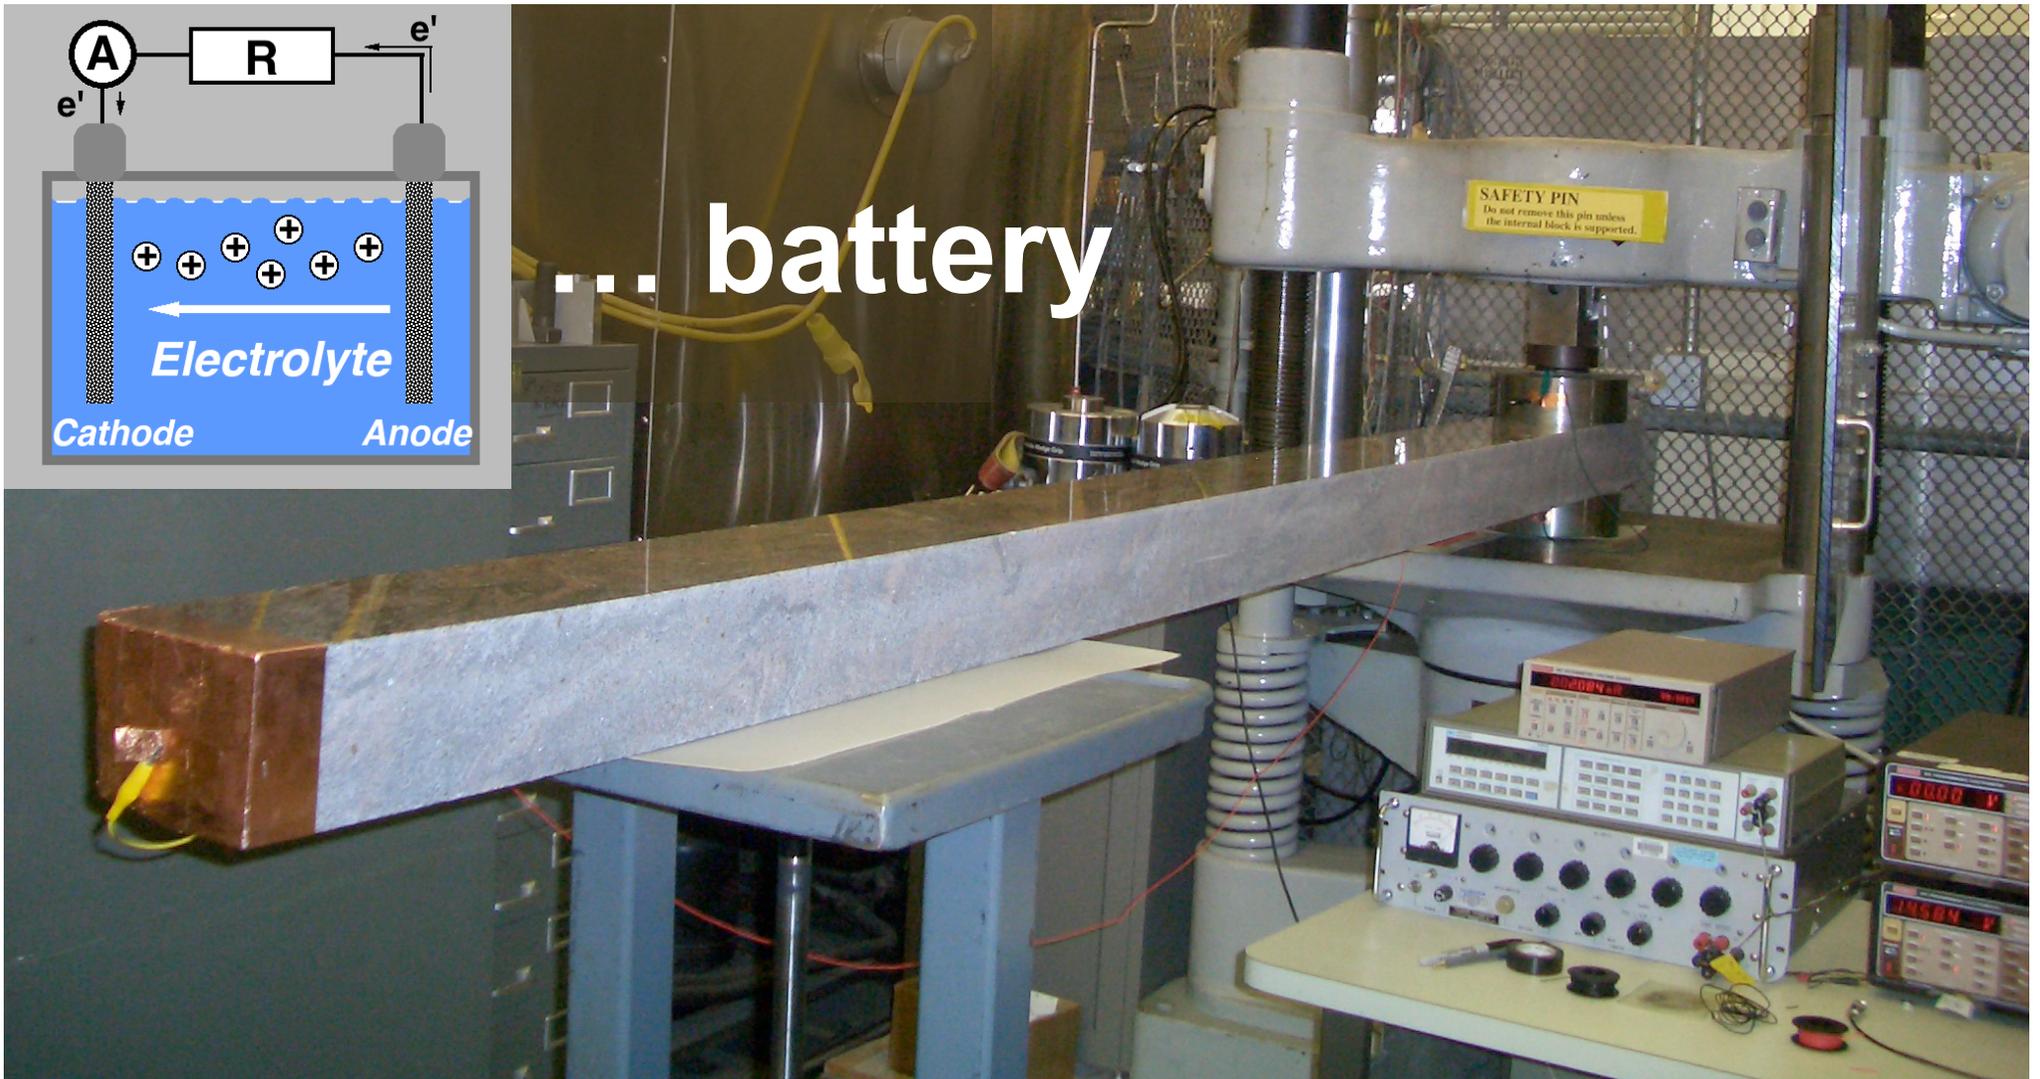

4 m long slab of granite squeezed at the far end

1. Electric current instantly starts to flow
2. Current saturates
3. Continues to flow at constant load
4. Current stops when unloaded
5. Can be repeated infinite number of times

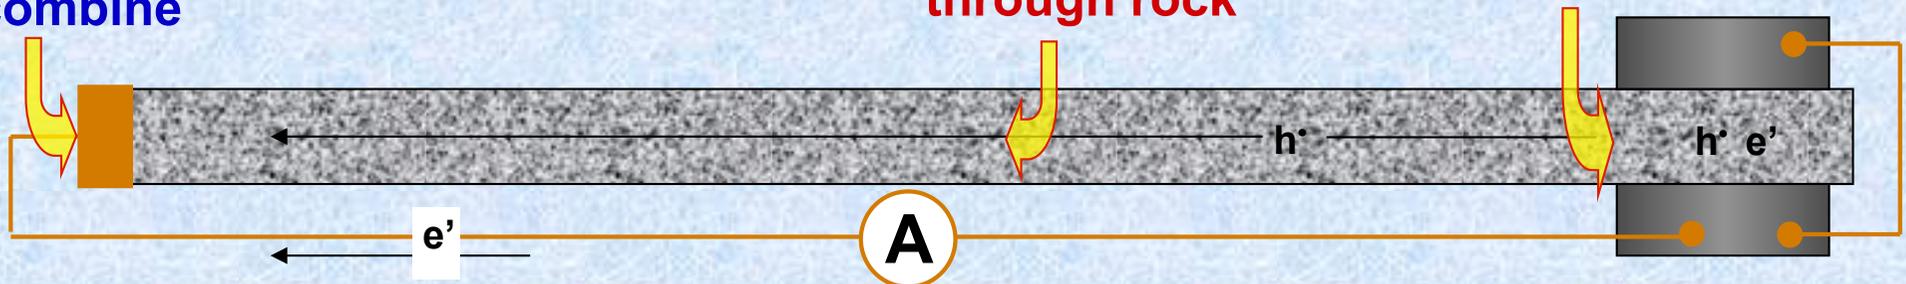

... battery

Electrons and holes recombine

Holes flow through rock

Activation volume: electrons and holes

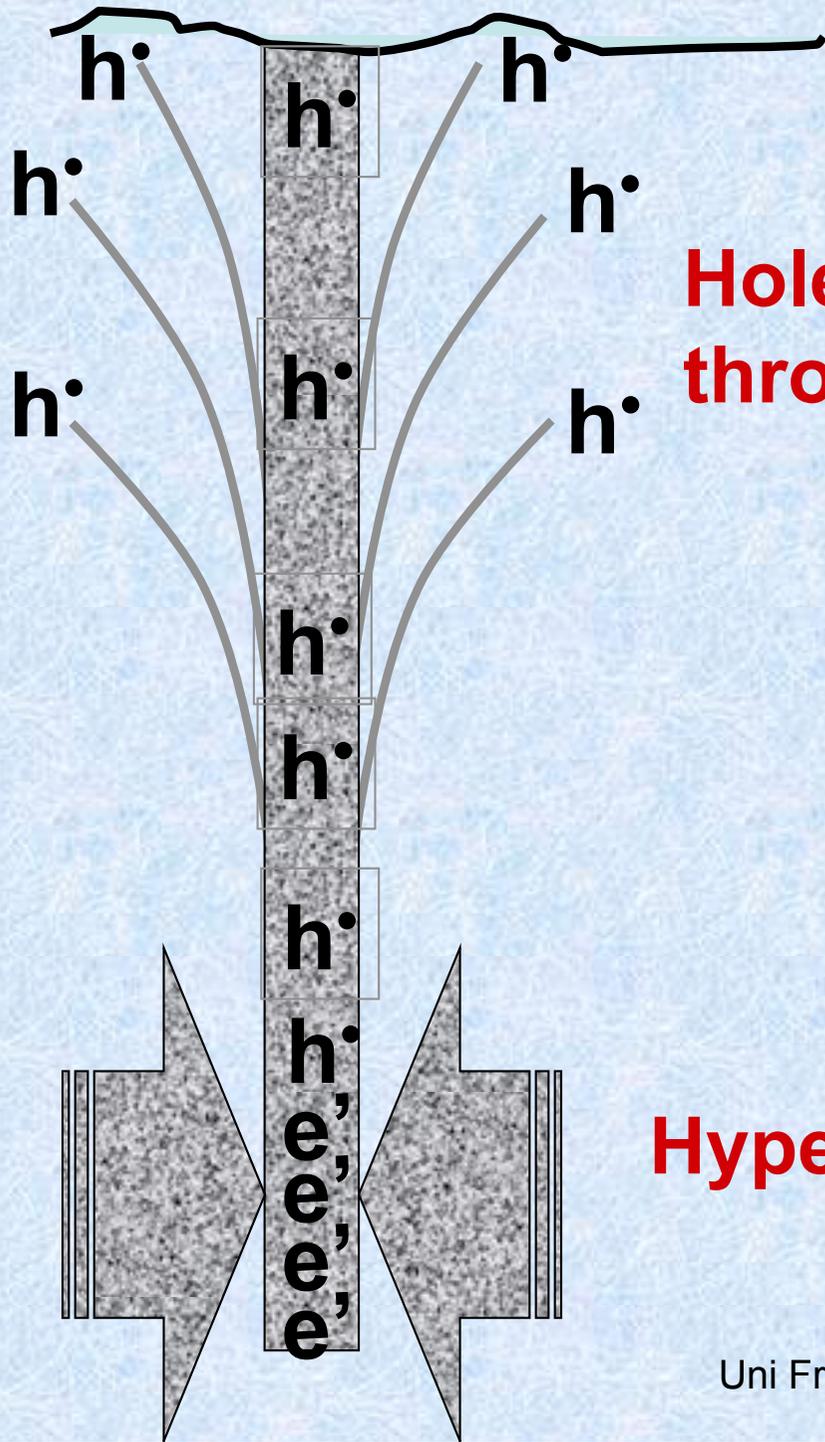

## **Question:**

**Is there anything in Nature that produces electric signals before major earthquakes?**

**Answer: Plenty.**

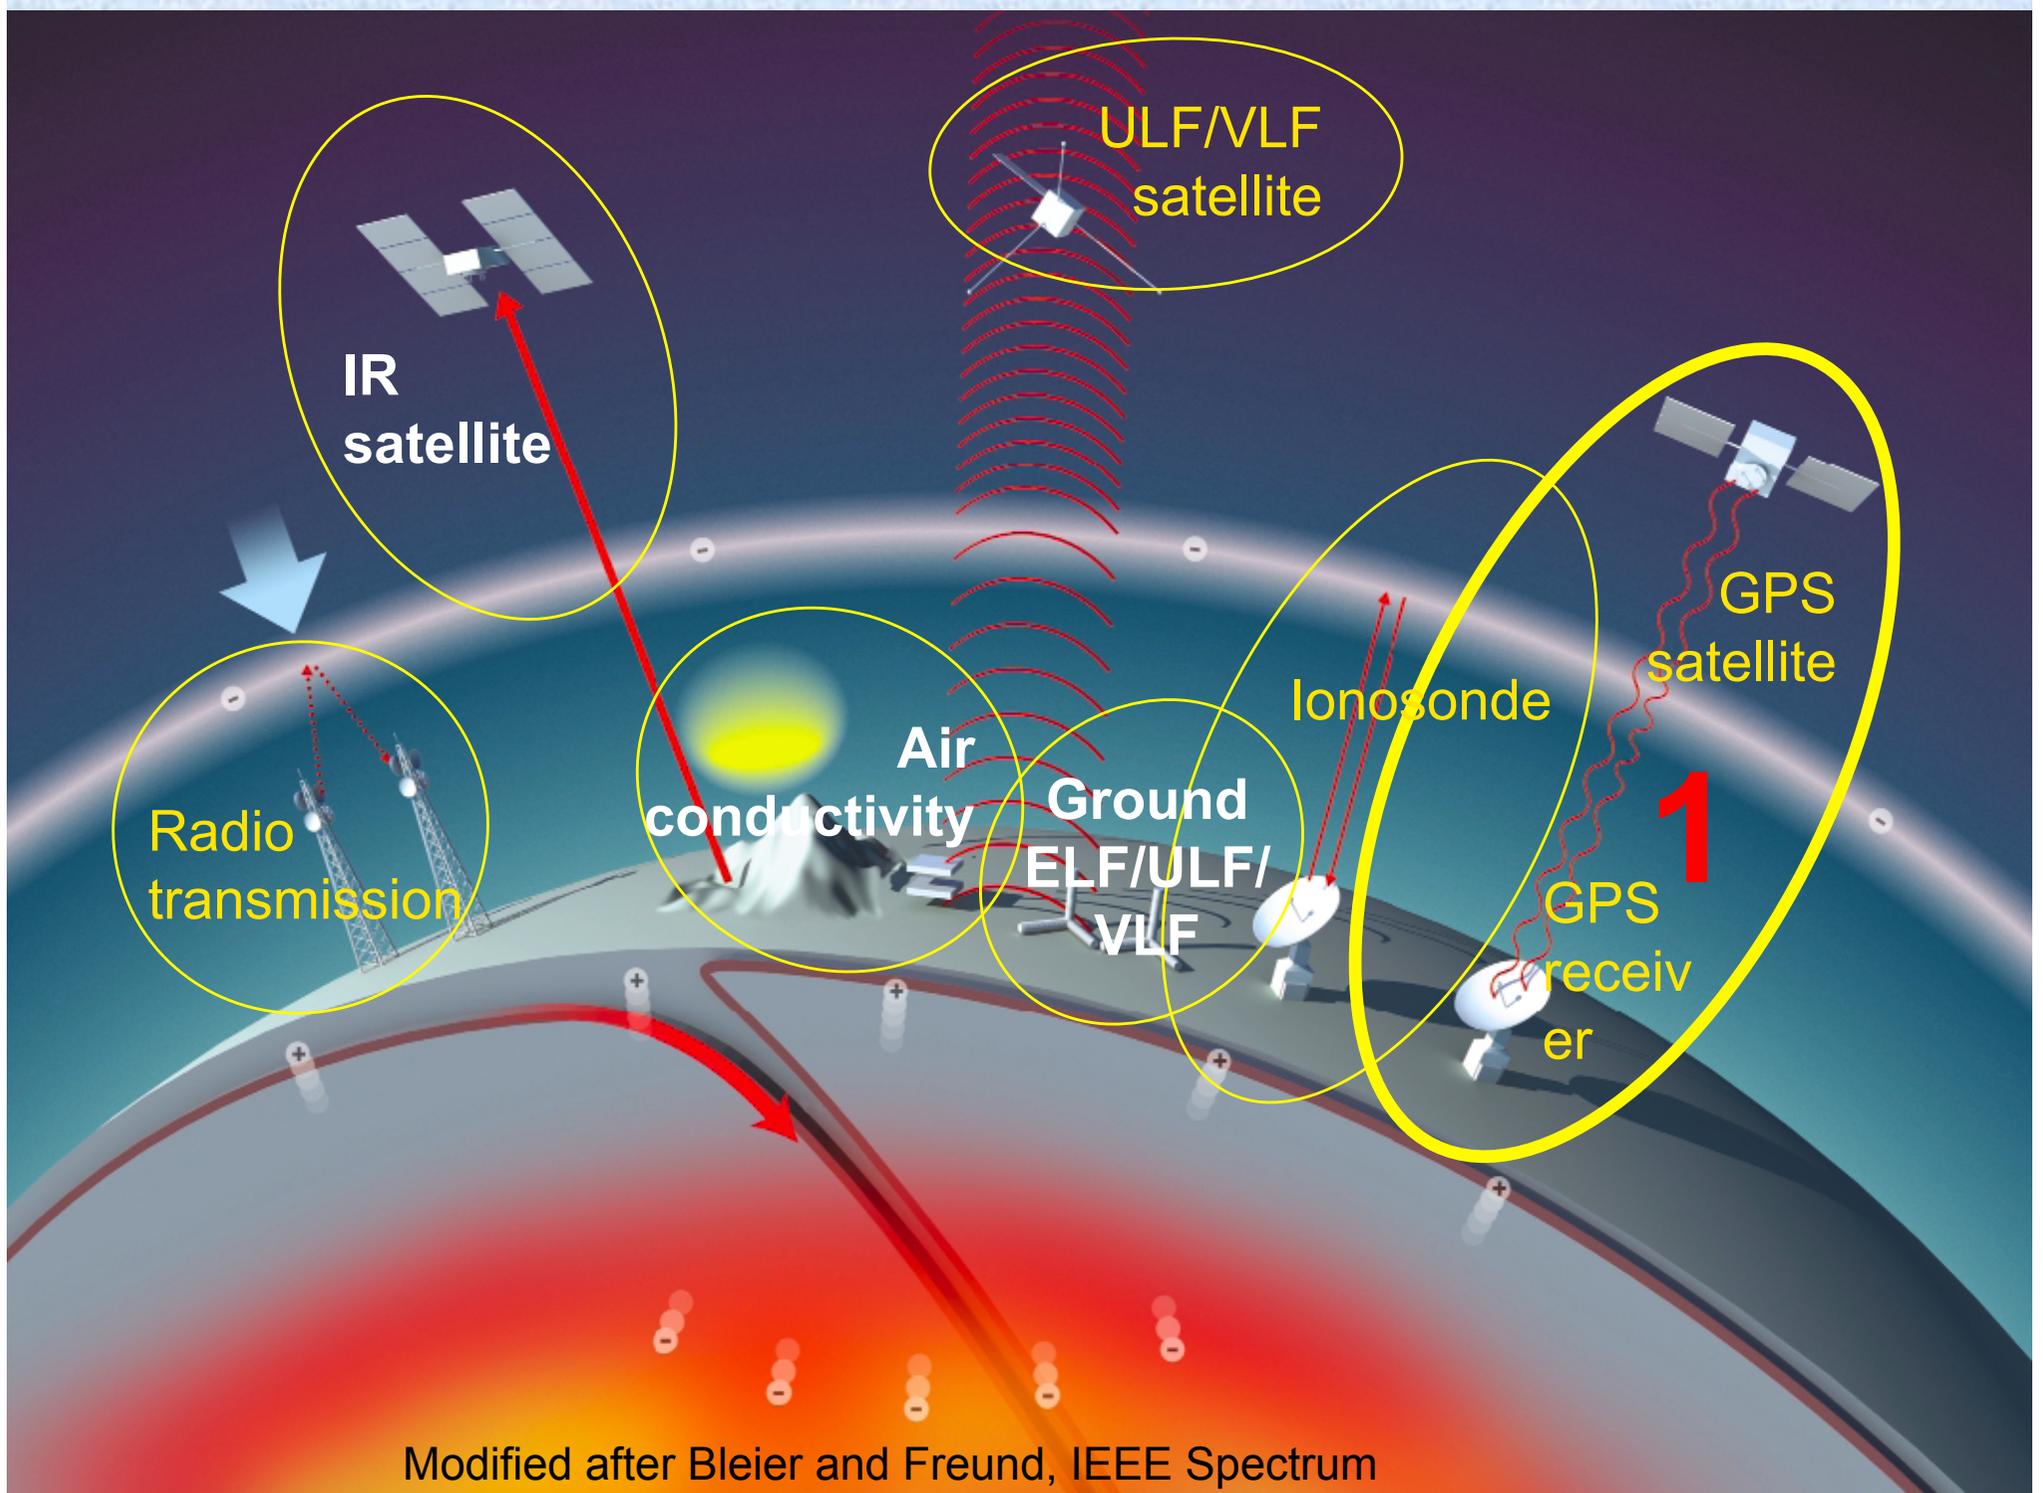

**Earth surface**

**Holes flow  
through rock**

## **Battery Currents**

**Hypercenter 10-35 km below**

Modified after Bleier and Freund, IEEE Spectrum  
2005

Ground ELF/VLF/VLF

Ionosonde

GPS receiver **1**

Modified after Bleier and Freund, IEEE Spectrum 2005

**If positive holes accumulate  
at Earth surface, what else can they do?**

**...they can ionize the air**

**massive positive  
air ionization**

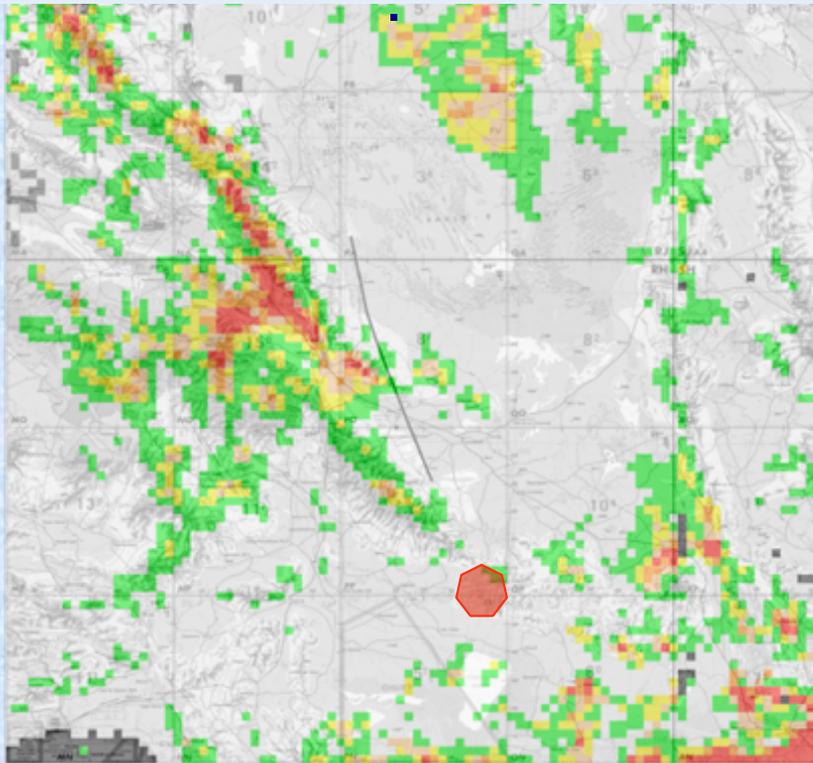

**If positive holes accumulate  
at Earth surface, what else can they do?**

**...they can recombine, returning to the  
peroxy state:**

**Infrared emission**

a final thought...

# Future Disaster Management Cycle

**The basic physics that controls the  
generation of pre-EQ signals  
has been solved,  
(at least in its most important aspects)**

**We are ready to begin implementing  
Global Earthquake Forecasting System**

# Actionable EQ Forecasting System

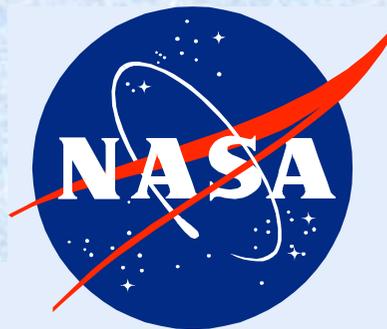

- **is possible**
- **lies within technical reach**
- **will combine many more pre-EQ signals**
- **will provide 24-48 hrs warning**
- **is financially attractive**
- **would be politically smart**
- **economically, it's a no-brainer**

# Conclusions

- Positive hole charge carriers exist in Earth's crust
- Positive holes are activated by stress
- Positive holes have lifetimes from subsecs to hrs
- **Positive holes hold the key to understand a wide range of pre-earthquake processes**
  - inside the crust
  - at the ground-to-water interface
  - at the ground-to-air interface
  - all the way up to the ionosphere

# Hyperspectral 7-14 $\mu\text{m}$ Imager

- **Proposal by Aerospace Corp (13-IIP13-0066)**  
P.I. David Tratt, Sci-P.I. Friedemann Freund
- **Cost: \$4M over 3 yrs**
- **In the meantime we can do Night-time Thermal Gradient Maps with existing weather satellites**
- **Cost: \$0.8 to 1.2M/yr**

1. **Ionosphere anomalies** ~~These~~ are detectable typically 3-5 days before major earthquakes. The anomalies in the ionosphere consist of increases in the Total Electron Concentration (TEC) at the lower edge of the ionosphere, best measured during night-time when the effects of the solar radiation on the ionosphere are fading away. They can be recorded by at least three techniques (i) using existing GPS technology to reconstruct a tomographic images of the ionosphere over seismically active regions; (ii) using “over-the-horizon” FM radio wave transmission to detect changes in the morning or evening terminator times; and (iii) using long-distance AM radio waves reflected off the ionosphere over the seismically active region.
2. **Thermal Infrared (TIR) anomalies** ~~TIR anomalies~~ consist of increases to (i) the radiative temperature of the ground and (ii) the radiative temperature at the top of the clouds, also known as Long Wavelength Infrared anomalies. TIR anomalies mark the impending earthquake’s epicentral region and become detectable typically 3-5 days before major earthquakes. They can be detected by various satellite-borne infrared cameras or by hyperspectral infrared imagers. Medium resolution detection is currently possible using MODIS data on the NASA satellites TERRA and AQUA, providing one data point during the day and one during the night per each 24-hour period. Even low resolution detection is possible using geostationary weather satellite data by determining the slope of the night-time cooling curves from IR images every 15-30 min. Satellite with hyperspectral capabilities are not yet available but AeroSpace Corp is interested in developing such an imager for geostationary deployment.
3. **Anomalous CO** release from the ground is currently retrievable from the MOPPIT sensor onboard the NASA satellites TERRA and AQUA providing one daytime data set per 24 hours.
4. **Increase in positive and negative air ion concentrations** using networks of ground stations typically 100-200 km apart.
5. **Changes in the total magnetic field intensity**, x, y, z-components to be measured by ground stations less than 100 km apart.
6. **Emission of ultralow frequency (ULF) electromagnetic (EM) waves** from the ground. Both of these unipolar pulses typically last 100 msec to 1-2 sec., Continuous ULF wave trains last minutes to hours, and their x, y, z-components can be measured by ground stations typically less than 100 km apart.
7. **Regional changes in radio frequency noise** at different frequencies from very low to medium low (VLF-LF).
8. **Soil resistivity changes** can be detected 1-2 m deep as measured by 4-point ground electrode systems, less than 100 km apart.
9. **Radon emanation** from the ground by stations, typically less than 100 km apart.
10. **Changes in water chemistry** at commercial natural spring water bottling companies or from ground water wells, typically less than 100 km apart.
11. **Noticeable changes to the circadian rhythm studies** being carried out 24/7 at universities, hospitals and zoos, using well-kept laboratory animals.
12. **Hospital records** with emphasis on increasing numbers of Emergency Room calls related to central nervous system disorders.
